Test Vectors

- 4-D Data hyper-cube signal intensity vs time, frequency, polarisation.
- Examples of real astrophysical signals (periodic (pulsars) and transient (FRBs, GP, RRATs)).
- SKA sized test vectors are up to 36GB based on current requirements.
- Crucial for
 - demonstrating pipeline performance
 - demonstrating compliance to system requirements
 - ad-hoc/unit/system/pipeline testing

Test Vector

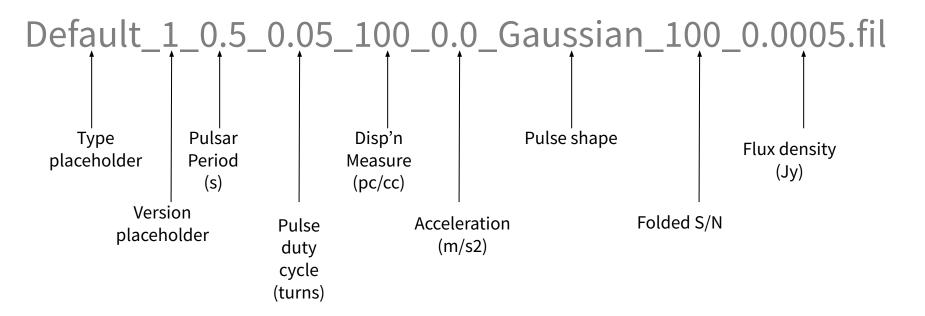

Shortcomings

- Test vectors are name according to their properties but some traceability information is missing (e.g., which version produced them?).
- Old versions of vectors need to be retained and "latest" versions need to be easily available.
- Directory structure needs to reflect different vector types that will be available for download]
- Cheetah configs are name arbitrarily need some standard (or some method of generating them on-the-fly)

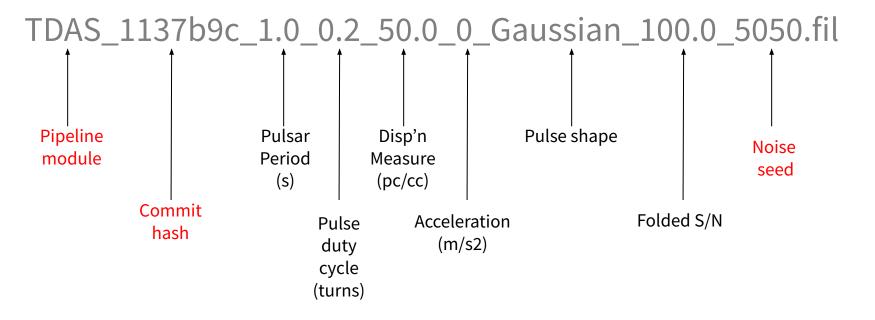

Tickets

- AT4-559 Establish new name convention for PSS test vectors
- AT4-560 Update PSS test vector generator to conform to new naming standard
- AT4-561 Establish directory structure for new test vector repository on dokimi
- AT4-562 Update PSS test vector generator to publish test vectors to repository on dokimi
- AT4-563 Establish naming convention for cheetah config files

AT4-559 Establish new name convention for PSS test vectors

AT4-559 Establish new name convention for PSS test vectors

AT4-561 Establish directory structure for new test vector repository on dokimi

- Previously, vectors have been generated on an ad-hoc basis when required.
- Here we set up a formal repository for test vectors on our test-vector server dokimi (located at JBO)
- Requirements
 - Should include all available vectors for a range of pipeline module tests
 - Be exposed to the web for testers/gitlab pipelines to download vectors as required
 - Should be easy to maintain and modify/add to
 - "Latest" versions should be available but older versions should be retained

AT4-563 Establish naming convention for cheetah config files

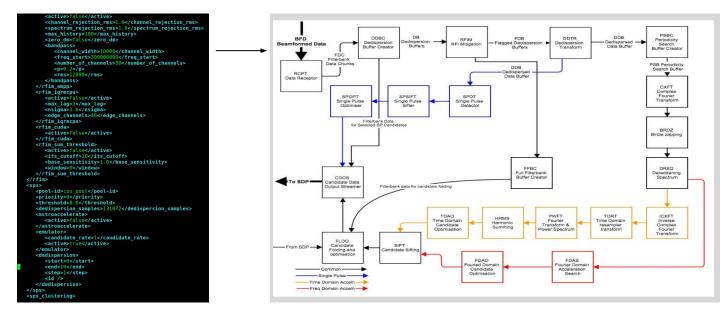

We don't have a convention at all currently for naming cheetah config files.

Configured by xml/json input

All (sub-)components are configured here

Huge number of parameters/possibilities.

Difficult to meaningfully name these files or understand the files contents without inspection

AT4-563 Establish naming convention for cheetah config files

- Pipeline tests will require large numbers of distinct configurations
- These may be similar in purpose (with subtle differences between them, e.g., to test edge cases)

Good news:

- Cheetah itself can generate config file templates.
- We will create a (set of) python class(es) that will generated and populate configuration files "on-the-fly" as part of the setup for a forthcoming test.
- This make us immune from changes to cheetah configs

File names: cheetah_config_<ID>.xml

Where ID is a testID.

Feature planned for future PI: See SP-1914

DEMO

To come

- Many more features planned to design/build the cheetah testing framework
- See Lina's demo on our single pulse search (SPS) test vector generation and validation for testing our radio transient detection pipeline
- Dokimi isn't publicly exposed to the web need a reverse proxy (in progress + next PI).
- Where will the test vectors *ultimately* live?
 - What backend app do we need to parse queries and supply vectors? Flask? Something else?
